

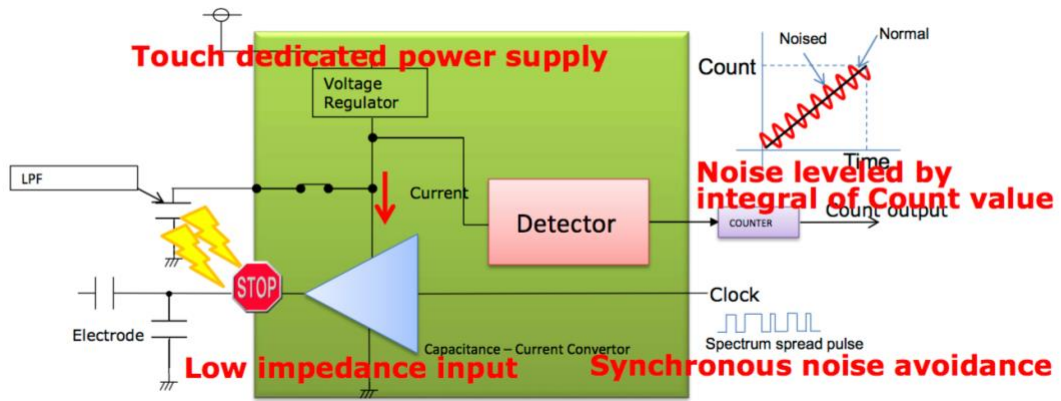

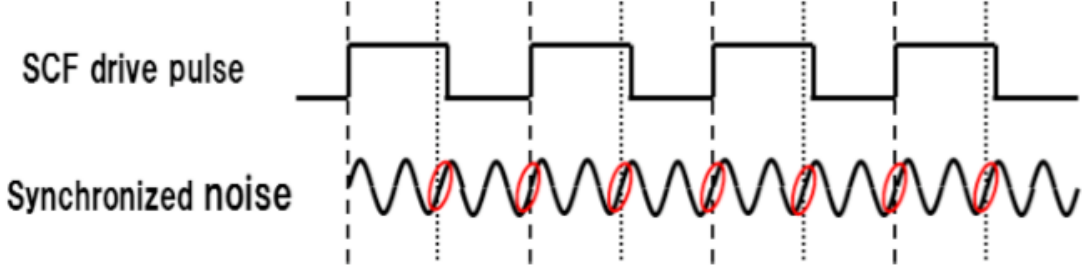

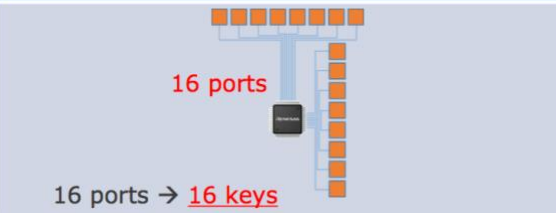

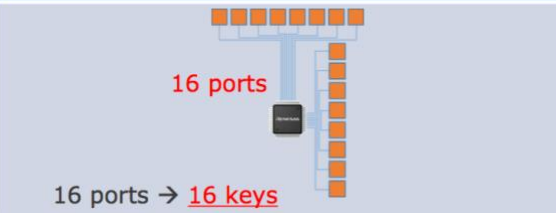

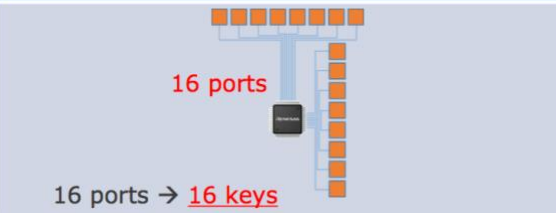

Exhibit 5

U.S. Patent No. 8,253,706 (“’706 Patent”)**Exemplary Accused Products**

Renesas products, including at least each of the following products (and their variations) infringe at least Claim 1 of the ’706 Patent: Renesas RX microcontrollers with capacitive touch, such as RX113, RX231, RX230, and RX130. The infringement chart below is based on the RX113 microcontroller (“RX113 MCU”), which is exemplary of the infringement of the ’706 Patent.

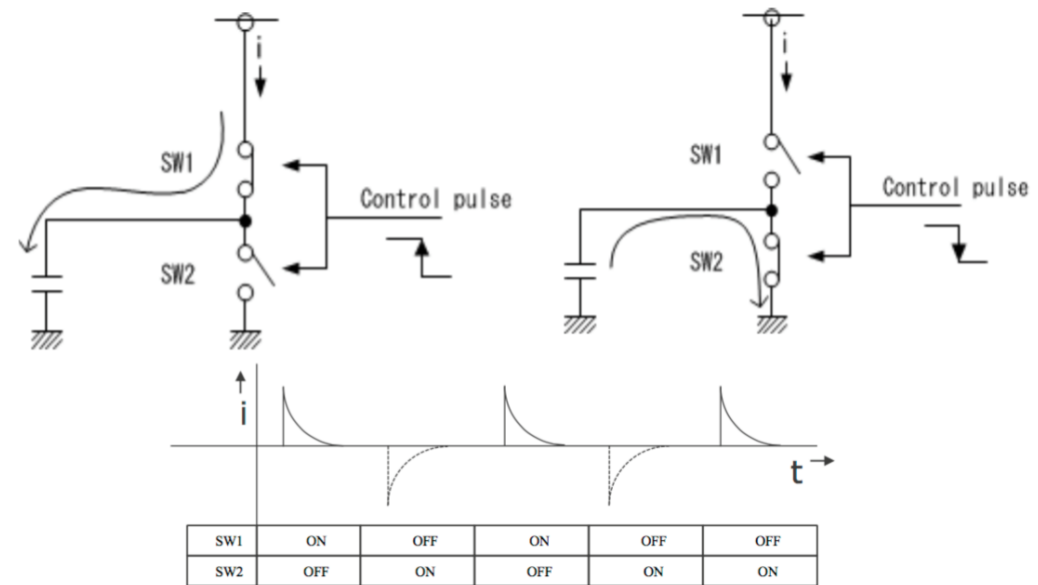

| Claim | RX113 MCU |
|-----------------------------|---|
| [1pre] A method comprising: | <p>The RX113 MCU provides capacitive touch sensing functionality, including in noisy and moist environments.</p> <p>For example, the RX113 MCU controlled touch sensor may exhibit noise sources impacting signal to noise (SNR) parameters. RX113 MCU utilizes multiple measurements to filter effects of the noise sources.</p>  <p>The diagram shows the internal components of the RX113 MCU for capacitive touch sensing. A 'Touch dedicated power supply' feeds into a 'Voltage Regulator'. The output of the regulator goes to a 'Capacitance – Current Converter' (represented by a blue triangle). The input to this converter is labeled 'Low impedance input' and is connected to an 'Electrode' through a 'STOP' symbol (indicating a break or connection point). A 'Current' arrow points from the converter to a 'Detector'. The detector's output goes to a 'COUNTER', which produces a 'Count output'. A 'Clock' signal, shown as a 'Spectrum spread pulse', is also input to the counter. To the right, a graph plots 'Count' on the y-axis against 'Time' on the x-axis. It shows a 'Normal' signal as a straight line and a 'Noised' signal as a jagged line. A red arrow points from the noisy signal to the counter, with the text 'Noise leveled by integral of Count value'.</p> <p>See Cap Touch and 3D gesture solution, at p. 21, http://img.cheerue.com/D5C994E3-F0CF-4E81-676E-B20D75A511B0_thinkv_2018-09-14_5b9b7417cfbb0.pdf.</p> |

In the mutual-capacitance method, a transmission node and a reception node are used to generate an electromagnetic field, and changes in the electromagnetic field between these nodes are detected (Figure 3). With this method, liquid that comes into contact with the operating surface has almost no effect on the electromagnetic field. Thus, this method can be used even in environments where the operating surface is likely to get wet. In addition, in a self-capacitive touch sensor system where electrodes are arranged in a matrix (grid), a false ghost detection occurs if two or more points are touched at the same time. A mutual-capacitive touch sensor system does not have this issue. Thus, a mutual-capacitive system uses a small number of pins to configure many electrodes, and supports multitouch behavior and more sophisticated operations than simple on (touch) and off (not touching).

[1b] acquiring a second response from the output line of the matrix touch screen, the second response being a capacitively induced signal derived from a falling

The RX113 MCU acquires a second response from the output line of the matrix touch screen, the second response being a capacitively induced signal derived from a falling edge of the pulse applied to the input line of the matrix touch screen.

edge of the pulse applied to the input line of the matrix touch screen; and

For example, the RX113 MCU acquires a second signal during the falling edge of conversion clock.

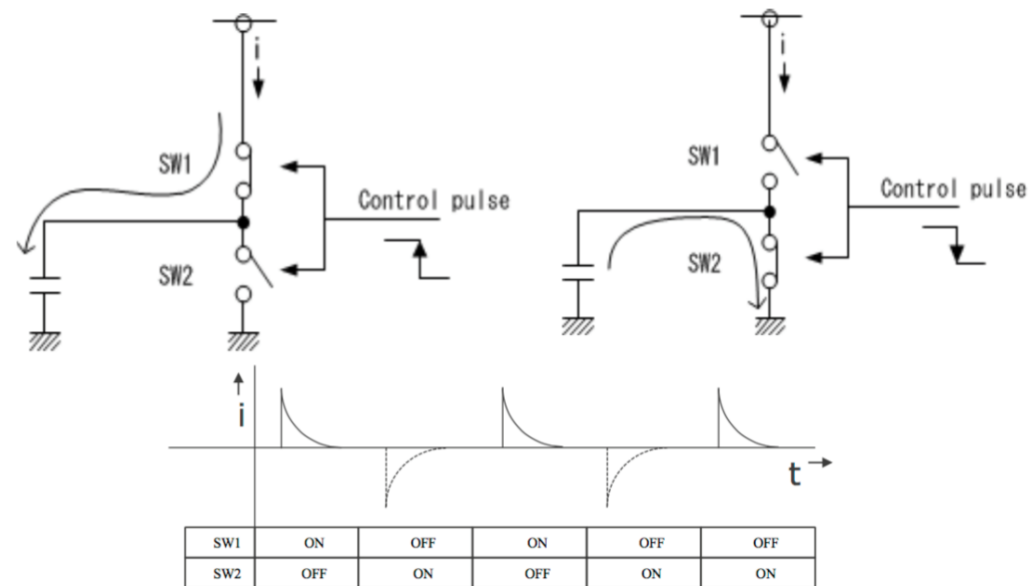

Increase cap touch key channels by matrix

[1c] manipulating the first response and the second response to reject noise at frequencies less than a frequency associated with the pulse.

The RX113 MCU manipulates the first response and the second response to reject noise at frequencies less than a frequency associated with the pulse.

For example, the RX113 MCU manipulates current (noised) measurements which include the first and second responses to reject noise having low or at the touch sensor's operational frequency.
